

# A Look at the REPRO3 Orbits

---

SVOD WG Meeting 2022

Tim Springer

28/06/2022

ESA UNCLASSIFIED – For ESA Official Use Only

- Investigated the systematic effects between the AC orbits
  - Try to reduce the draconic terms in our products
    - Must be coming from orbit modelling errors
  - Defined “minimal requirements” for the orbit model for repro3
    - And routine solutions
- Evaluate REPRO 3 results
  - For 2010 (II, IIA), 2015(IIR, IIF) , and 2020 (IIF, IIIA)
  - ACs: COD, ESA, GFZ, GRG, JPL, MIT, NGS, TUG, WHU
    - 6 ACs including GALILEO
  - Combined IGS orbits also included
  - Also a first look into Galileo results

- IGS Routine Orbits from 2018
  - Differences for IIR larger than for IIF
  - COD, ESA and JPL use “enhanced” models
    - For IIR these are in agreement, for IIF not
- IGS REPRO-2 Orbits from 2014
  - Similar results for IIR and IIF as observed in 2018
  - Also significant differences for II/IIA but smaller than for IIR
- Presentation and Position paper from 2019 AC Workshop available
  - on the google drive of this session

**Due to highly systematic nature of these differences they hardly show up in the RMS differences of orbit comparisons**

- The JPL GSPM model may be used for all GPS satellites
  - Not available for GLONASS nor GALILEO
- ECOM2 is certainly to be preferred over the ECOM approach
  - Some issues for the IIF
  - Not optimal for GLONASS
- IGS/ESA box-wing approach also better than ECOM
  - For those who used it for Earth Albedo (and IR?) it should be easy to do
- All three models will still result in draconic periods in the IGS products
  - But we should see a clear improvement

- Very good agreement for the GALILEO IOV satellites
  - Those are easier to model!
- Significant differences for the “eccentric” GALILEO satellites
  - Expected as one per revolution ECOM terms do not work very well
  - ECOM2 not adequate for these two satellites
- Very significant differences for the GALILEO FOC satellites
  - Not really expected
  - But they are harder to model than the IOV satellites
    - Most likely due to heat radiators on the  $-Z$  side
    - And GNSS transmit antenna working like “heat sink” giving a significant periodic force in the  $Z$ -direction.
- Significant work needed to get the results more similar!

# Z-Geocenter REPRO2

# Z-Geocenter REPRO3

- Significant improvements for the different GPS satellite block types!
  - Thanks to all the ACs who put effort into this!
- GPS Block IIIA shows significant differences
  - In particular radial component improvements needed!
- Significant differences for GALILEO observed
  - Expected for the eccentric satellites
  - Less expected for the FOC satellites -> work needed!
- Clearly the REPRO-3 orbits still have significant systematic orbit differences
  - Consequently, the IGS products will and do still show signals with frequencies related to the orbit periods
- We have done a good step forward but more needs to be done

**Much more effort needs to be put into improving the RPR modeling of the GNSS satellites to reduce the spurious draconic terms in the IGS products!**

# The End
