$u^{\scriptscriptstyle b}$ Genesis mission

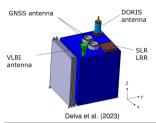

- 1 satellite with instruments for 4 space geodetic techniques GNSS, SLR, DORIS, VLBI, space ties
- Aim: Contribute to an improved International Terrestrial Reference Frame
- Approved at ESA's Ministerial Council in 2022, part of FutureNAV, launch in 2028

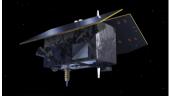

@esa

genesis

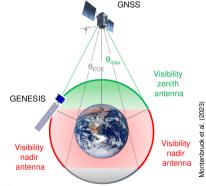

$oldsymbol{u}^{\scriptscriptstyle b}$ Genesis satellite and orbit

- 6000 km altitude polar orbit (VLBI visibility)
- → received GNSS signals emitted at nadir angles up to 28° (max. 14° on ground, 17° in LEO)
- Zenith- and nadir-pointing GNSS antennas

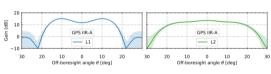

Kur et al. (2024) (DOI 10.1007/s00190-024-01869-8) have studied the benefit of Genesis for Galileo orbit and clock determination.

$oldsymbol{u}^{\scriptscriptstyle b}$ GNSS challenges & aim of the study

At nadir angles as large as 28°

- only limited information (gain, phase and pseudo-range variations) on GNSS transmit antennas available
- the GNSS signal strength might be problematic (drop of gain)

Montenbruck et al. (2023)* have analyzed the GNSS visibility for Genesis and presented comprehensive link budget simulations to simulate realistic GNSS data.

*: DOI 10.1007/s00190-023-01784-4

Question

How do uncertainties in GNSS transmit antenna phase variations (PVs) at large nadir angles affect the contribution of Genesis to global TRF solutions?

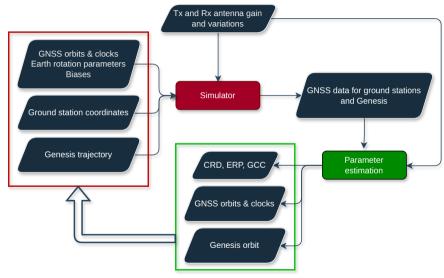

N.b.: In-flight calibrations weaken GNSS contribution to TRF realization!

u^b Methods

u^b Methods

$u^{\scriptscriptstyle b}$ Ground stations

Selection of 100 IGS ground stations:

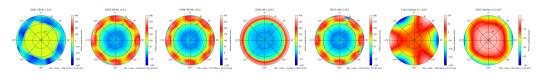

$u^{\scriptscriptstyle b}$ Antenna phase patterns

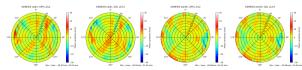

Ground stations: IGS20.ATX

GNSS satellites:

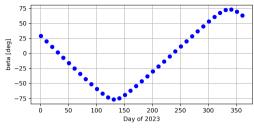

- GPS: LMB20 antenna model (Montenbruck et al., 2024, DOI 10.1007/s00190-023-01809-y)
- Quadratic extrapolation of published patterns from 20 $^{\circ}$ to 30 $^{\circ}$ nadir angle for Galileo

Genesis: Sentinel-6A patterns

$u^{\scriptscriptstyle b}$ Simulation

- Day 001, 011, ..., 361 of 2023 (37 days)
- Genesis orbit (5957 km, 95.5°): Dynamic orbit propagated using radiation pressure models based on 8-plate macro model for box and wing and nominal yaw attitude
- GNSS products: CODE final orbits, clocks, ERPs, biases
- Station coordinates: IGS cumulative SINEX, PSD, ITRF2020 seasonal harmonics, solid Earth tides, pole tides, ocean loading
- Ionosphere: CODE GIMs (ground stations), NeQuick-G (Genesis)
- Troposphere: GPT/GMF model

u^{\flat} Estimation

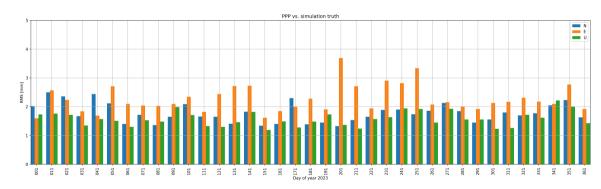

- Undifferenced GNSS data processing
- Carrier phase ambiguities fixed in PPP-AR
- Estimated parameters:
 - Station coordinates
 - Earth rotation parameters
 - Geocenter coordinates
 - Site-specific troposphere parameters
 - GNSS satellite orbits
 - GNSS satellite clocks
 - Genesis orbit (initial cond. and constrained 30' piecewise-const. acc.)
 - Station and Genesis receiver clocks
 - Observable-specific code biases
- Data sampling: 180 s (→ about 83'000 parameters/day)
- Code and phase data for ground stations, only phase data for Genesis (\rightarrow about 1'800'000 observations/day)

Procedures: Kobel et al. (2024), DOI 10.1016/j.asr.2024.04.015

"Zero" test: Coordinates

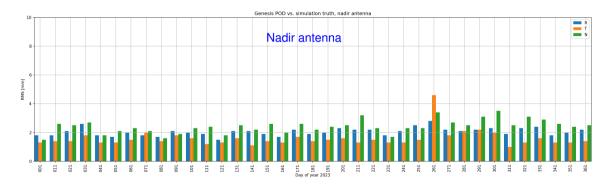

PPP (only estimate station-related parameters) using CODE final GNSS products and the correct transmit PVs. Differences to "true" coordinates:

Same order of magnitude as differences between different IGS ACs (e.g., 4.10/3.32/2.76 mm for CODE vs. ESA for day 23/001) → realistic model uncertainties

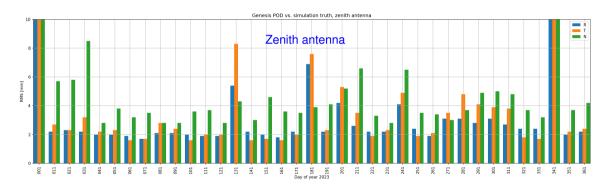

$u^{\scriptscriptstyle b}$ "Zero" test: Genesis orbit

Genesis POD using CODE final GNSS products and the correct transmit PVs. Differences to "true" Genesis orbit:

$u^{\scriptscriptstyle b}$ "Zero" test: Genesis orbit

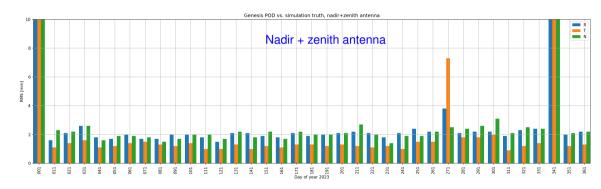

Genesis POD using CODE final GNSS products and the correct transmit PVs. Differences to "true" Genesis orbit:

Zenith-antenna based POD more challenging

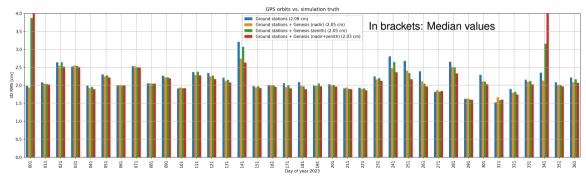

$u^{\scriptscriptstyle b}$ "Zero" test: Genesis orbit

Genesis POD using CODE final GNSS products and the correct transmit PVs. Differences to "true" Genesis orbit:

$\mu^{\scriptscriptstyle b}$ Full parameter estimation: GNSS orbits

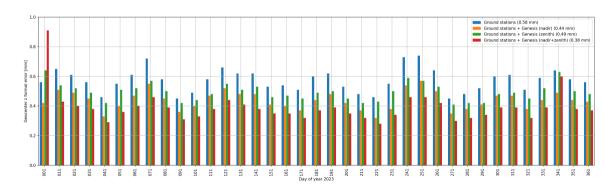

Estimating orbit and geodetic parameters using ground stations and Genesis data and correct transmit PVs. Differences of estimated GPS orbits compared to "true" orbits:

 Notice: The "true" orbits (CODE final) are 3-day orbits, while here only 1-day orbits are computed (→ slightly degraded comparison).

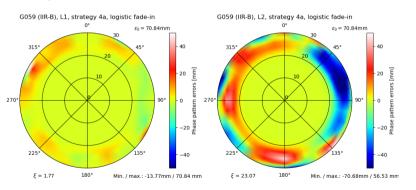

Full parameter estimation: Geocenter

Formal errors of geocenter *z* coordinates, using correct transmit PVs:

$oldsymbol{u}^{\scriptscriptstyle b}$ Phase pattern errors

Derive transmitter phase pattern errors by scaling differences of single patterns w.r.t. block-specific mean values:

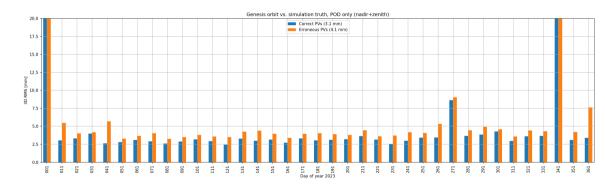

Errors zero for small nadir angles.

Add these pattern errors to the true transmit PVs in the parameter estimation

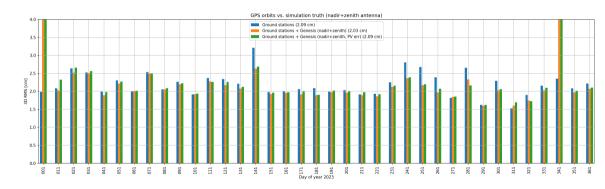

$oldsymbol{u}^{\scriptscriptstyle b}$ Impact on Genesis orbit

Genesis orbit differences from a POD-only solution:

Impact on GNSS orbits

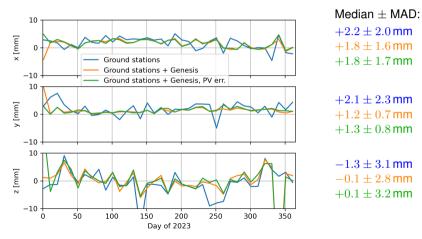

Differences of estimated GPS orbits compared to "true" orbits:

Slight degradation of GNSS orbits, benefit of Genesis reduced

Impact on geocenter coordinates

Estimated geocenter coordinates (nadir+zenith antenna):

Conclusions

- The GNSS tracking of Genesis is less straightforward than for LEOs (especially zenith) antenna).
- Established a simulation framework to study impact of systematic GNSS modeling errors on orbit and global solutions.
- Supposedly realistic GNSS transmit phase pattern errors counteract the potential benefit of Genesis on GNSS orbits and geocenter coordinates.
- To fully exploit Genesis for TRF contributions, characterizations of GNSS transmit antennas up to large nadir angles should be known/made available to the extent possible!

Thank you!
